

Docker Setup

I'm assuming you have docker installed already. All good. I would be creating a folder into which we will create a sub-folder for every docker app you want to run.

You *can* just create one massive docker-compose.yml and put every app inside that, but from my experience, it gets hard to manage.

On my system, I have the following layout:

```
apps/  
├─ home-assistant  
├─ jellyfin  
└─ traefik
```

I have a whole bunch of other apps, too, but you get the idea.

So in principle, every folder for an app will have a docker-compose.yml file in it. (Once the container has started, it's likely that it will create a bunch of other stuff in that folder, too.)

You're going to be running a LOT of docker compose commands. It gets boring typing that shit out all the time, so I would recommend creating a few shell aliases for example:

```
alias dc='/usr/bin/docker compose'  
alias dcf='/usr/bin/docker compose logs -f'
```
